

wEXOS: is a "wrapped token", acting like a bridge to ethereum that connects our two chains together economically. The way that you do that is you create a version of your token like a mirror copy that can run on that other blockchain. These are called wrapped tokens. [Answer from Kent if we can use some of the definitions: The process of wrapping a token is the process of making it operable in another blockchain's economy. It's an interface between the EXOS and the Ethereum blockchains, providing interoperability between the two. wEXOS is an ERC20 token [a token on the Ethereum blockchain] which has a 1 to 1 representation on the EXOS blockchain which is a separate blockchain. It allows you to leverage the smart contract functionality on Ethereum, the positives of another blockchain ecosystem but maintain the rule-bound approach, the history, everything that you and Nayib spent time architecting very carefully for your community from day one.] The idea has been to create systems of wallets that people can put their EXOS into and get wEXOS in return.
